

# Dynamics of Ecosystems

---

---

---

---

---

---

---

---

- Ecosystem - All the organisms in an area that interact with each other and with their environment of energy and matter.
- Sunlight is captured by green plants during photosynthesis and stored as chemical energy.
- The energy passes through the ecosystem from species to species when herbivores eat plants and carnivores eat herbivores.
- These interactions form food chains.

---

---

---

---

---

---

---

---

- All organisms in an ecosystem have a specific role or trophic level:
  - Producer – convert radiant energy into chemical energy for ecosystems (green plants)
  - Primary consumers – animals that eat plants (herbivores)
  - Secondary consumers – animals that eat other animals (carnivores)

---

---

---

---

---

---

---

---

# The Carbon Cycle

---

---

---

---

---

---

---

---

## The Carbon Cycle

- In the carbon cycle, carbon and oxygen move back and forth between living things and their surrounding environment.
- Consists of two processes:
  - Photosynthesis
  - Cellular Respiration

---

---

---

---

---

---

---

---

## Photosynthesis

- Occurs in all plants
- Converts carbon dioxide and water to carbohydrates (sugar) and oxygen
- $6\text{CO}_2 + 6\text{H}_2\text{O} + \text{energy} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$

---

---

---

---

---

---

---

---

## Cellular Respiration

- Converts oxygen to carbon dioxide
- Carried out by all living cells
- $6\text{O}_2 + \text{C}_6\text{H}_{12}\text{O}_6 \rightarrow 6\text{CO}_2 + 6\text{H}_2\text{O} + \text{energy}$

---

---

---

---

---

---

---

---

## Carbon Cycle for a Terrestrial Ecosystem

---

---

---

---

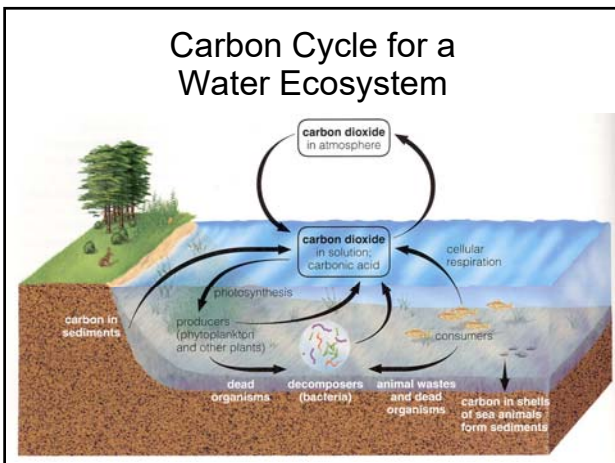

---

---

---

---

## Carbon Cycle for a Water Ecosystem

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Nitrogen Fixation

- Plants use Nitrogen (N), Phosphorus (P), and potassium (K) for growth.
- These elements are found in plant fertilizer.
- How do plants get Nitrogen if they are not given fertilizer?
  - From the atmosphere.
  - The Earth's atmosphere is 80% Nitrogen
- But....

---

---

---

---

---

---

---

---

- Most plants cannot absorb nitrogen directly from the air.
- The nitrogen must first be "fixed" :
  - Pulled from the air and bonded to other elements to make new compounds
- This process is called **nitrogen fixation**.
- For example, nitrogen can combine with hydrogen to form ammonium ( $\text{NH}_4^+$ ) or oxygen to form nitrate ( $\text{NO}_3^-$ )

---

---

---

---

---

---

---

---

- Plants absorb the nitrogen compounds through their roots
- Animals can obtain nitrogen only by eating plants or other animals.

---

---

---

---

---

---

---

---

- In nature, the job of nitrogen fixation is carried out by a few species of nitrogen-fixing bacteria.
- Rhizobia (most important)
  - Live in the nodules (rounded swellings) on the roots of legumes (peas, beans, alfalfa, clover)
- Before the development of artificial fertilizers, farmers planted legumes in their fields to help restore the fertility of the soil

---

---

---

---

---

---

---

---

- Once Nitrogen has been fixed it enters the soil and water where it becomes available for living organisms to use.
- Nitrogen compounds that enter plants move through food chains and return to the soil and water through dead organisms and waste materials
- These compounds can re-enter plants without being converted to Nitrogen gas.

---

---

---

---

---

---

---

---

- In an aquatic ecosystem nitrogen fixation is carried out by cyanobacteria, also known as blue-green algae.

---

---

---

---

---

---

---

---

### Nitrification

- Decomposers, such as bacteria, break down the waste and dead materials producing ammonia.
- Ammonia is used directly by some plants as a source of nitrogen.
- Ammonia is also converted into nitrates by nitrifying bacteria in a process called **nitrification**.

---

---

---

---

---

---

---

---

- The nitrates in the soil or water may be converted back into nitrogen gas by denitrifying bacteria.
- This process is called **denitrification**.

---

---

---

---

---

---

---

---

## Nitrogen Cycle in a Terrestrial Ecosystem

---

---

---

---

---

---

---

---

## Nitrogen Cycle in an Aquatic Ecosystem

---

---

---

---

---

---

---

---

## Disturbing the Cycles

- What factors may disturb these cycles?
  - Overuse of fertilizers and herbicides
  - Combustion of fossil fuels
  - Deforestation
  - Human and animal waste mismanagement
  - Volcanic activity
  - Forest fires

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Bioaccumulation

- increase in concentration of a pollutant from the environment in the first organism in a food chain
  - the pollutant is stored in the organism rather than being expelled as waste

---

---

---

---

---

---

---

---

### Biomagnification

- increase in concentration of a pollutant from one link in a food chain to another

---

---

---

---

---

---

---

---

- For bioaccumulation and biomagnification to occur, the pollutant must be:

- Long-lived
  - stays in the environment more than 15 years before it breaks down
- Mobile
  - if it stays in one place it can be easily contained
- Soluble in fats
  - it is absorbed and retained by animals
- Biologically active
  - it affects biological organisms

---

---

---

---

---

---

---

---

### DDT

(dichloro, diphenyl trichloroethane)

- DDT has a “half-life” of 15 years
  - If there is 100kg, then after 15 years 50kg remains
  - After 30 years 25kg remains
  - After 90 years 1.56kg remains
- DDT is fat soluble and is stored in the bodies of organisms
- DDT has low toxicity in humans, but kills insects

---

---

---

---

---

---

---

---

### Other Substances that can Biomagnify

- PCBs (polychlorinated biphenyls)
  - Uses:
    - coolant in transformers
    - sealing and caulking compounds
    - inks and paint additives
  - Problems:
    - severe form of acne (chloracne), swelling of the upper eyelids, discoloring of the nails and skin, numbness in the arms and/or legs, weakness, muscle spasms, chronic bronchitis, and problems related to the nervous system

---

---

---

---

---

---

---

---

• PAH (polynuclear aromatic hydrocarbons )

- Uses:
  - component of petroleum products
- Problems:
  - possible carcinogen

---

---

---

---

---

---

---

---

• Heavy metals (mercury, copper, cadmium, chromium, lead, nickel, zinc, tin)

- Uses:
  - mercury from gold mining
  - many from metal processing
- Problems:
  - may affect nervous system
  - may affect reproduction

---

---

---

---

---

---

---

---

• Cyanide

- Uses:
  - leaching gold from ore
- Problems:
  - toxic

---

---

---

---

---

---

---

---

- Selenium

- Uses:

- plays a key role in metabolism

- Problems:

- liver, kidney and heart problems
- at high enough levels it is toxic

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Population Size

- Population can increase due to:

- Natality

- Offspring added to population

- Immigration

- Individuals moving into the area

- Population can decrease due to:

- Mortality

- Individual dies (eaten, sickness, old age)

- Emigration

- Individuals moving out of the area

---

---

---

---

---

---

---

---

## Population Growth

- Population growth goes through three phases:
  - Exponential
    - Quick growing when there are very few limiting factors
      - Plants germinating in spring
  - Transitional
    - Slowing of growth rate as the population approaches the carrying capacity
  - Population plateau
    - The population remains constant or stable
      - Note: the plateau may have variations year to year around an average value

---

---

---

---

---

---

---

---

## Population Growth Curve

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

## Carrying Capacity

- The largest population of a species that an environment can support is called the **carrying capacity**.
- Four main factors affect carrying capacity:
  - Materials and energy
  - Food chains
  - Competition
  - Density

---

---

---

---

---

---

---

---

## Materials and Energy

- All populations of organisms are ultimately limited by amount of usable energy from the sun, as well as the supply of water, carbon, and other essential materials.

---

---

---

---

---

---

---

---

## Food Chains

- The population size at any trophic level is limited by the population (or biomass) in all the levels below it.
- Populations are limited by food.
- Populations are also limited by organisms in the trophic levels above them.
- Animal populations are limited by predators.
- Plant populations are limited by herbivores.

---

---

---

---

---

---

---

---

## Competition

- Each organism has the same needs as other organisms.
  - Food, water, mates, space
- This demand results in competition.
  - Foxes in an area may eat rabbits for lunch. A rabbit population is low and the fox population is high, competition for food among foxes increases.

---

---

---

---

---

---

---

---

- Competition among members of the same species is called **intraspecific competition**.
  - Foxes in an area may also compete with wolves and coyotes for rabbits.
- Competition between species is called **interspecific competition**.
  - All of the herbivores in an area compete for the same food.
- Both intraspecific and interspecific competition can limit population growth.

---

---

---

---

---

---

---

---

## Density

- Different species have different needs for space depending on their size, environment and way of life.
  - Grizzly bears space themselves out
  - Penguins live together in large groups
- This need for space determines an organism's **population density**.
  - How many individuals can live in an area at one time.

---

---

---

---

---

---

---

---

- If a population density increases beyond a suitable level for a particular species, conditions are produced that tend to limit growth.
  - Overcrowding may increase the spread of disease or parasites
  - Overcrowding in some species increases aggression and neglect of offspring (increases death rate and lowers birth rate)
- Factors that increase in significance as a population grows are called **density-dependent factors**.

---

---

---

---

---

---

---

---

- Other factors can limit a population, regardless of its size.
  - A forest fire may kill most of the snakes in the forest, whether there are 10 or 10 000 of them.
- Such factors are called **density-independent factors** because their effect on population size does not depend on how many individuals there are in the population.

---

---

---

---

---

---

---

---
